INTRODUCTION

Biomass offers a potentially ideal source of fuel for cleaner power generation and the support of sustainable development in developing countries. It is the fourth largest source of primary energy in the world and the largest source of renewable energy, supplying about ten percent of 2004 total primary energy supply. Biomass could account for in excess of thirty percent of the world’s primary energy by the year 2050.

Biomass power generation technology is mature, yet deployment of this technology on a wide scale faces significant institutional barriers related to the difficulty associated with sourcing a reliable and affordable supply of biomass. Biomass power production at a large scale also poses significant water and food security issues if not managed properly.

The authors review China and India’s laws and policies regarding biomass supply in order to assess their institutional arrangements for application of biomass technology. We selected China and India for study because they are the world’s largest countries in terms of population, their economies and energy demand are rapidly growing, and they have large agricultural sectors. Biomass will be increasingly important to these countries as they seek to meet energy demand in a sustainable manner.

This article examines the advantages of biomass energy for developing countries; the barriers posed by difficulty in obtaining an economical, adequate, and reliable supply of biomass; and how China and India have prepared for biomass generation by addressing these barriers through legislation. It describes policies and programs developed by China and India to encourage expansion and integration of this important technology into the existing energy infrastructure.

ADVANTAGES OF BIOMASS FOR DEVELOPING COUNTRIES

In developing countries, biomass typically accounts for as much as twenty to thirty percent of energy supply and in a number of countries can reach fifty to ninety percent of total energy supply. In these countries, biomass is used as the primary source of energy for home heating and cooking in rural areas. However, the burning of biomass, which typically occurs in enclosed areas, poses threats to human health, and is a primary cause of respiratory diseases in developing countries.

Biomass electricity generation can provide household energy without the adverse health impacts of using biomass directly in homes. Further, biomass power generation can significantly reduce sulfur dioxide and nitrous oxides, mercury, particulate emissions, and greenhouse gas (“GHG”) emissions compared to coal power plants. Coal currently supplies eighty percent of China’s power, and sixty-nine percent of India’s power. As is well-known, pollutants from coal power plants cause serious health effects, such as birth defects, as well as cancer and respiratory illness; they also pollute land and water and poison food supplies.

Biomass power generation can also help reduce the use of chemical fertilizers in agricultural production and promote the development of organic agriculture. The ash product of a biomass power plant can be processed into fertilizer for use by farmers. In turn, the greater reliance on organic fertilizers can reduce the negative effects of chemical fertilizers on soil and ultimately significantly promote water conservation.

For China, estimates for the amount of agricultural biomass available range from approximately 250 to 376 million tons per year, out of a total of approximately 726 million tons of crop residue generation. This could supply cooking fuel for over half a billion people. China’s forests produce additional bio-

mass residue of about 24.77 million cubic meters per year using sustainable forest management practices.\textsuperscript{14}

For India, biomass has long been the main energy source for cooking and heating. India produces approximately 500 million tons of biomass per year.\textsuperscript{15} Biomass has emerged as an increasingly attractive option for power generation due to the growing demand for power, recurrent power shortages throughout the country, a projected shortage of coal for power generation, and the high cost of diesel and other fossil fuels.

Biomass electricity generation plants could potentially help farmers by providing supplementary income from their farm waste to aid in stabilizing farming communities and land use patterns and provide permanent and seasonal employment in rural areas. Biomass for electrification should be integrated into existing property and cultural patterns without requiring the consolidation of small farms into larger operations.

If planned properly, biomass power plants should be able to use only waste biomass that would not require additional water or displace food crops. Further, biomass plants using waste should favor food security by increasing income to rural farmers and keeping land in production. However, if the adoption of biomass power generation changes indigenous agricultural practices, the biomass power plant could potentially require additional water resources or require land that otherwise would produce food to convert to fuel production.

*Figure 1: India’s Estimated Annual Biomass Production*
Biomass also faces significant transaction costs resulting from the quantities of biomass required to be collected from large numbers of farms. Contracts with small farmers for a guaranteed supply of biomass would not likely be commercially practicable or enforceable, given that natural conditions play a major factor in biomass production and enforcement costs would be prohibitive.

Further, biomass electricity generation competes with many other uses of biomass. As noted, in developing countries, biomass is commonly used for home heating and cooking in rural areas, and it is burnt by farmers to help fertilize growing fields. Other sources of competition include use by ranchers as a source of feed for livestock, use as a source of supply for construction materials such as bricks and roofs, and use by the paper industry as a source of material for making paper.

In addition to market barriers to biomass, there are also environmental and resource barriers. For example, the availability of water for growing crops such as sugarcane or for cooling a power plant can limit the introduction of biomass power generation in certain geographic areas.

**Biomass Supply and Cost Impacts on Project Financing**

Biomass supply requirements for a small-size power plant are substantial. The financial performance of a biomass plant is highly sensitive to the cost of biomass supply. In order to assess the risks associated with fuel supply, we conducted a financial analysis based on the retrofit of a coal plant to a biomass-fueled combined heat and power plant in China.

The financial analysis assumes electricity is priced based on preferential rates provided pursuant to China’s Renewable Energy Law, but that no additional subsidies are considered. The project financial analysis further assumes that Clean Development Mechanism certified emission reduction certificates are sold by the project for 90 renminbi (“RMB”) per metric ton carbon dioxide for a three-year period.

We calculate that a combined heat and power biomass power plant with energy capacity of 24 Megawatts (“MW”) requires 270,000 tons of straw (assuming a moisture content of twenty-five percent) per year. Such a power plant would require three ten-ton truckloads of biomass every hour continuously in order to operate at full capacity.

Based on the average size of farm in China (approximately 3 mu, or 0.002 square kilometers), we estimate that each farm produces 1.2 to 1.8 tons of straw per year, and that the power plant will require straw from an average of 180,000 farms. In our example, supply must be sourced within a 75 km radius of the plant so that transportation costs are acceptable, however the cost and risk to the plant increases with distance. A plant operator would likely require much shorter distances to ensure profitability. Further, in terms of sustainability, we estimate that more than half of all transportation related carbon emissions in biomass production can be avoided if the supply is located within 25 km of the power plant.

In rural China, the average annual income in 2005 was 3,255 RMB per year. If straw could be sold for 125 RMB per ton, we estimate that the average farm supplying 1.5 tons of straw per year could increase their annual income by almost 200 RMB/year, an increase of almost six percent that could be very helpful to a low-income household.

The project’s financial performance is highly sensitive to the price of straw. For our hypothetical 24 MW project, a 25% increase in the price of straw reduces the project’s the internal rate of return (“IRR”) on equity from 28.4% to 21.5% and the debt service coverage ratio (“DSCR”) from 2.25 to 2.02, assuming a 70% debt-to-equity ratio. In contrast, a one million RMB increase in initial costs slightly decreases IRR on equity from 28.4% to 28.3%, and the DSCR from 2.25 to 2.24.

While our example still shows very good returns, the increase in straw price can result in a significant reduction in profit, and ultimately cause a marginal project to fail. If the market is thin or fragmented, as is typical, the potential for local biomass prices to spike as a result of the introduction of a biomass power plant are real and could render the project uneconomic.

Figure 2: Financial Analysis of Combined Heat and Power Biomass Power Plant in China

*Note: The improvement in financial results for a 3 MW power plant results from the use of more efficient technology that is currently only available on smaller scales.*
POLICY AND REGULATORY FRAMEWORKS IN CHINA AND INDIA

We review China and India’s laws and policies regarding biomass supply in order to assess their institutional arrangements for application of biomass technology.

CHINA

China’s National Development Reform Commission set targets for development of renewable energy, including 30 GW of biomass renewable energy to be built by 2020. In support of this goal, the country has developed a series of laws, regulations, and policies with the intention of achieving this substantial increase in biomass use.

China’s Renewable Energy Law supports various kinds of renewable energy, including biomass, through a system of preferential electricity prices that vary on a regional basis. The law also provides additional payments for electricity generated with low sulfur emissions. Subsidies for biomass electricity and desulfurization abatement equipment terminate after 15 years. The Renewable Energy Law guarantees sale of renewable electricity to the power grid.

China also offers various financial incentives for biomass. This includes subsidies supporting R&D, low interest loans to projects, and grants to rural households for wood-stoves and bio-gas systems. China also provides tax incentives, including reduced customs taxes for imported equipment and an income tax holiday for industries whose main inputs are wastes.

All land and natural resources in China are owned by the state, and leased to land users. China’s property laws and regulations do not, to our knowledge, contain any provisions providing for biomass to be supplied to power generators. China does, however, forbid the direct burning of crop residues within the vicinity of roads, and railway and transportation infrastructure.

The measure is intended to increase the utilization of crop residues as fertilizer, materials for industrial use, and straw and stalk gasification.

China’s Ministry of Finance issued the Interim Measures for Administration of Special Funds for the Development of Renewable Energy in May 2006 to fund studies, standards formation, resource surveys, production of equipment, and construction of projects in remote areas in the field of renewable energy, including biomass and biofuels. The funds provide both cash appropriation and subsidized loans. The Ministry of Finance and the Ministry of Construction issued the Interim Measures for Administration of Special Funds for Using Renewable Energy in Construction in September 2006. This fund provides financial support to renewable energy, including biomass, used in construction of buildings, such as biomass energy to be used for heating and cooling systems, hot-water supply, electricity for lighting, and cooking.

The Ministry of Finance issued the Notice of Interim Measures on Subsidy Funds for Using Straw as Energy Resource in 2008. This “Special Fund for Straw” supports enterprises that convert crop straw into energy, including densification briquetting fuel, straw gasification, and straw carbonization. In Chinese law, straw includes paddy rice, wheat, corn, legumes, vegetable material that can be pressed to extract oil, cotton, and tuber crops and remains produced during the initial processing of crops. To be eligible for support from the Special Fund for Straw, the following requirements must be satisfied:

- Enterprise must have registered capital of RMB 10 million or more;
- Enterprise’s utilization of straw as energy resource conforms to local regulations governing general utilization of straw;
• Enterprise’s annual straw consumption is at least 10,000 tons; and
• Enterprise’s products are commercialized and have stable customers.

China’s energy technology subsidies programs are intended to increase the efficiency of biomass power generation and integrate it with buildings (a major power user), which will help make biomass power generation less expensive and more financially stable. The Special Fund for Straw is intended to directly address the risks associated with biomass supply. However, these subsidies are likely to be temporary in nature. Thus, the long-term strategy should be to increase efficiency of biomass technologies, and to adapt technologies to the conditions of the biomass market.

INDIA

In 1981, India created a government commission with overall responsibility for developing renewable energy and a separate Department of Non-Conventional Energy Sources in the Ministry of Power that eventually evolved into the Ministry of New and Renewable Energy. The Ministry of New and Renewable Energy issued the Renewable Energy Power Purchase Guidelines to all States in 1993, followed by the Energy Conservation Act of 2001, which mandated adoption of standards and procedures and prescribed measures for energy conservation. The Electricity Act of 2003 guaranteed interconnection for renewable energy sources and provided recommendations for preferential tariffs and quotas for renewable generation. Almost all states have implemented some form of preferential tariffs for renewable energy generation, and have set general quotas for renewable energy, but have not specified quotas by energy type. The amount of subsidies depends upon the type of technology used in the project and the equipment’s level of efficiency. These measures have been strengthened by the National Electricity Policy of 2005, the Tariff Policy of 2006, the Rural Electrification Policy of 2006, and the Integrated Energy Policy Report of the Planning Commission of India in 2006. Today, India’s power market mostly comprises regulated prices with a few states introducing open bidding on electricity through ten to fifteen year power purchase agreements.

In addition to preferential rates specified by the state regulatory authority and guaranteed grid access, a number of cash and tax subsidies are available to aid in the development of biomass. Federal subsidies are available to developers of biomass power plants. The amount of the subsidy depends upon the efficiency rating of the plant. The government exempts imported and domestic equipment from excise duties, and offers accelerated depreciation treatment for energy efficiency and biomass power generation equipment. Finally, the government offers a 10-year tax holiday that applies to biomass power plants.

Regarding the natural resources available for the facilitation of biomass development, abundant sugarcane bagasse is the main raw material for biomass power generation in India. India is the world’s second largest sugarcane producing country, following Brazil. In India, bagasse electricity production is generally combined with the production of sugar, with a portion of the electricity used to power the mill, and the excess sold into the grid. The cogeneration of power with sugar production strengthens the overall financial condition of the project.

In order to promote sufficient biomass supply for each facility, sugarcane mills are required to be located a minimum distance from each other by state law. For example, in Uttar Pradesh, India’s leading sugar cane growing region, mills may not be located within a 15 km radius of each other.

CASE STUDY: INDIA

WATER-EFFICIENT SUGARCANE FARMING IN INDIA

Sugarcane is traditionally a water-intensive crop, requiring steady irrigation for a full eighteen-months to two-year growing period. Without abundant local water resources, sugarcane requires extensive irrigation that competes against other food crops and can be costly both financially and ecologically. Conventional sugarcane farming also relies heavily on fertilizers and pesticides.

An innovation pioneered by a local farmer in Karnataka, India, replaces the practice of soil flooding with providing enough water to maintain soil moisture. The method involves reducing the number of irrigation channels, building up the soil’s organic content and earth fauna, eliminating synthetic fertilizers and pesticides, and adopting no-till practices. Elimination of the water flood and these other changes enhance soil aeration and fertility, and reduce susceptibility to disease.

The method reduces water requirements by as much as seventy-five percent compared to conventional sugarcane farming, increases farming profits by eliminating costs of fertilizer and pesticides, better preserves the soil, and produces comparable or better yields.

Farming associations, such as the Organic Farmers Club, teach these and other techniques; however, these practices have yet to be institutionalized in government policy.

The Indian Renewable Energy Development Agency Limited (“IREDA”), a government-owned corporation that promotes, develops and finances renewable energy and energy efficiency projects, requires biomass power plant seeking financing to demonstrate that, for each MW of nameplate capacity, a plant will have access to at least 10,000 tons of biomass material each year in close proximity to the plant, and an additional 10,000 tons of surplus in the surrounding area. As a general guideline, in order to ensure supply of biomass, IREDA prohibits more than one biomass power plant in a single district and a minimum distance of at least 50 km between power plants. IREDA further requires that the quality of the biomass material have at least 2,000 kilocalories per kilogram. Finally, to be eligible for financing, the cost of the plant may not exceed U.S. $800 per KW nameplate capacity, depending upon boiler configuration and cooling system.

In the context of a private market, India’s laws provide a degree of protection from over-competition for supply of biomass; this is particularly important where land ownership is predominately private, as it is in India. Even with these protections, power plant owners still have ample incentive to pay a competitive rate for biomass supply, and to maintain good relationships with farmers. We are aware of examples of power plant owners providing their farm suppliers with financial assistance to purchase fertilizer, offering education on agricultural techniques, and even access to company health care facilities, schools, and other services.44

Endnotes: Overcoming Institutional Barriers to Biomass Power in China and India

1 Biomass includes crop residues, waste by-products of crop processing (e.g., rice straw, husk, wheat straw, coarse cereals, straws and husk, sugarcane bagasse tops, etc.), woody produce of forests and plantations, and biomass acquired from grows in wastelands.
